(54) Method for measuring the efficiency of a combustion and an apparatus for carrying out the method.

(57) A method and an apparatus for measuring the efficiency of a combustion whereby ash samples (2) are drawn at predetermined time intervals from a region of a combustion plant (3), each drawn sample is set in an exhausted reaction cell (4) wherein comburent containing reaction gas is introduced under controlled pressure and a superficial layer of said sample (2) is heated to the carbon combustion temperature by a CO<sub>2</sub> laser beam, the reaction gas is drawn from said cell (4) and the amount of carbon dioxide as produced by the carbon combustion is measured in a calibrated detector (16) in order to measure the amount of unburnt carbon contained in the ashes on the basis of a preceding colibration carried out on ashes of known carbon content.

EP 0 421 251 A2

# A METHOD FOR MEASURING THE EFFICIENCY OF A COMBUSTION AND AN APPARATUS FOR CARRYING OUT THE METHOD.

This present invention refers to a method for measuring the efficiency of a combustion, in particular a method for measuring in real time the content of unburnt carbon in the coal ashes and an apparatus for carrying out the method.

There are known chemical methods used in a laboratory for measuring the unburnt carbon amount in the ashes; such methods involve intricate operational sequences and long time periods which makes them not suitable to control a combustion in real time.

However, a method for the combustion control in real time allows to optimize the combustion and to get the consequent advantages as to energetic saving, high quality ash production and environmental pollution. Obviously, such a method has the additional advantage of allowing to control the combustion in transient state also or, anyway, in non standard operation conditions.

Through the techniques practiced so far for measuring unburnt material amounts in real time, ash samples are drawn through suitable flues in communication with a boiler and a property related to the unburnt carbon content is detected in the shortest possible time.

Examples of such known techniques are those that: are based on the optical analysis of samples wherein the heat depends on the elementary carbon content; measure the sample weight variation before and after heating in air since carbon develops by combustion; measure the reflection factor of a microwave signal since the dielectric constant of the ashes depends on their chemical composition.

All the above techniques are affected by great inaccuracy since the measured properties are related to the unburnt carbon content in an indirect and often non univocal way. Moreover, these techniques require that the amount of the ashes under test be known exactly and often require that considerable amount of material be drawn (tens of grams) which means extending the time necessary for measurement.

According to this invented method, as characterized in the appended claims, the measurement is carried out of the developed carbon dioxide and/or of the decrease of the oxygen in a reaction cell during a superficial and localized combustion caused by a laser beam in a small analysis ash sample. The coal ashes substantially consist of aluminium silicates presenting a strong absorption band in the mean infrared region wherein the CO<sub>2</sub> laser maximum gain line falls, which makes such laser suitable to this purpose; the laser beam is so well absorbed by said aluminium silicates that its

radiation is absorbed in a superficial layer of a few tenths millimeter thickness in said analysis sample and is converted into heat. It will be appreciated that the thickness of said layer depends on the ratio W/S between the laser beam power and the surface as hit by the same beam. Conveniently, said analysis sample will be some millimeters thick to prevent the heat produced by the laser from dispersing through the support whereon said sample is placed. The object of the laser beam is to heat a very small layer of ashes in the sample surface S rapidly (typically from 10 to 30 seconds) and locally upto high temperatures (700°C - 1200°C), depending on laser power. In an oxidative environment caused by introduction of air or oxygen as reaction gas the unburnt carbon reacts with oxygen and produces carbon dioxide; the reaction gas is drawn from the inside of the reaction cell and the CO<sub>2</sub> amount is measured by means of a detector suitable to such gas. An adequate preliminary calibration, carried out in the invented apparatus on calibration ash samples having known carbon content, enables to state a relation between the CO<sub>2</sub> amount as produced in said cell and the percentage content of unburnt carbon as contained in the analysis ash samples. In connection with predetermined laser beam specifications, the amount of the produced CO<sub>2</sub> is conditioned by the oxidative environment (gas pressure and kind). Obviously, the oxygen available in the cell shall be enough for completely burning the carbon as contained into the reaction ash volume. As an alternative or addition to the CO<sub>2</sub> analysis, the oxygen consumption during combustion in said cell is measured in order to measure the carbon amount burnt and contained as unburnt carbon in an analysis sample. Moreover, attention is drawn to the fact that the necessary analysis sample contains few grams of ashes, also two or three grams only.

According to known methods, said detector is associated with a programmer adapted at least : a) to drive the above described step sequence sequentially, i.e. at prescribed time intervals; b) to adjust the combustion plant operation according to a predetermined memorized program using the results of the analysis in said detector.

At least the following main advantages are afforded by this invention: directly detecting unburnt carbon amount through its transformation into CO<sub>2</sub>; no longer requiring an exact measurement of the amount of the ashes as drawn since the laser radiation is absorbed in a layer of few tenths millimeter thickness; rapidly measuring the amount of the unburnt carbon thanks to the kind of the heat

source and to the small amount of material to be drawn and analyzed; supplying a method and an apparatus for measuring the combustion efficiency in real time.

The invention will be described in detail herebelow with reference to the accompanying drawing which illustrates only one specific embodiment.

The apparatus comprises: a device 1 for sequentially drawing an analysis ash sample 2 from a region in a combustion plant 3 located between the ash precipitator and the air-preheater, both not shown in the drawing; a reaction cell 4 bearing a filter-support 5 to support said analysis sample 2; an oxygen source 6 in communication with the inside of said reaction cell 4 through a duct 7 to supply said cell with a controlled amount of oxygen under controlled pressure; a port 8 opposite to said filter-support 5 and closed with a plate 9 made of zinc selenide allowing the CO<sub>2</sub> laser beam to pass through; a baffle plate 10, located between said filter-support 5 and port 8, moved by motor means M between a closing position and the opening position shown in the drawing to protect said plate 9 from ash dust when analysis samples are introduced into the reaction cell; a CO<sub>2</sub> laser source 11 which directs the laser beam 12, through a lens 13 and a mirror 14, on a surface S of the analysis sample 2 set on the filter-support 5 in order to burn the carbon contained in a small layer of said surface S; an exhaustor 15 which draws the gas from said reaction cell and delivers it in a calibrated detector 16 able to measure the amount of CO<sub>2</sub> in the reaction gas (the detector is of the NDIR type, non-dispersive infrared photometer); a further object of said exhaustor 15 is to exhaust the reaction cell upto about 0.1 torr; an electric resistance heater 17 to remove possible humidity contained in the analysis sample 2; an ejector 18 to remove from the filter-support 5 and consequently from the reaction cell 4 the ash of the analysis sample at the end of the operation. All ducts D in the apparatus are controlled by solenoid valves V.

The operative means of the combustion plant 3 (fuel and air feeding, air and gas locks, registers, etc.), calibrated detector 16, motor means for the device 1, oxygen source 6, exhaustor 15, ejector 18, baffle plate 10, laser source 11, solenoid valves V and electric resistance 17 are all associated in a conventional manner with a micro-processor controller C adapted to drive at predetermined time intervals the described analysis cycle and to adjust the working of the operative means of the combustion plant 3 depending on the analysis result as supplied from the detector 16 according to a predetermined optimized combustion program. Wires w connect said controller C with all controlled parts.

The laser power ranges from 20 to 30 watts;

the diameter of laser beam on said surface S ranges from 8 to 15 mm; the analysis sample 2 has 4 mm thickness and 28 mm diameter; the reaction cell volume is 300 cm<sup>3</sup>. The heat absorption due to laser radiation ( $\lambda = 10,6 \text{ m}$ ) causes in the concerned material a temperature rise ranging from 900 °C and 1100 °C in a time period ranging from 10 to 15 seconds. The reaction gas in the reaction cell may be air or oxygen under a pressure ranging from 200 to 600 torr. Under said operative conditions and apparatus specifications, the amount of oxygen in said cell is enough to completely oxidize the ash volume as heated by the laser ( $2,5 \times 10^{-2} - 9,0 \times 10^{-2} \text{ cm}^3$ ) with a radiation time period ranging from 30" to 2". The range of the unburnt carbon percentages which may be analyzed by means of this apparatus is from 1% to 40%.

After laser radiation, the carbon development from said sample is evidenced by a clear spot on said surface S.

#### Claims

1. A method for measuring the efficiency of a coal combustion whereby an analysis ash sample (2) is serially drawn in order to analyse every time a property of the ashes related to the unburnt carbon content in said ashes, characterized in that it comprises the whole of the steps of: a) drawing each analysis ash sample (2) from a region of a coal combustion plant (3) and place said sample (2) on a filter-support (5) in a reaction cell (4) hermetically sealed under control; b) exhausting said reaction cell (4); c) supplying comburent gas under controlled pressure into said reaction cell (4); d) projecting on a surface (S) of said sample (2) a laser beam (12) of such kind and power that the laser radiation is absorbed by said ashes and heats a superficial layer of said sample (2) to at least the carbon combustion temperature; e) drawing the comburent gas together with the CO<sub>2</sub> as produced in said cell (4) by the combustion of that carbon contained in that part of said sample (2) heated by the laser beam and measuring the amount of said CO<sub>2</sub> in a first calibrated detector (16) in order to estimate the amount of unburnt carbon in the ashes on the basis of a preliminary calibration of the invented apparatus.

2. A method according to claim 1 characterized in that it comprises said steps a), b), c), d), e) and a step f) of drawing from said cell (4) the comburent gas together with the O<sub>2</sub> as residual of the carbon combustion, measuring the amount of said O<sub>2</sub> in a second calibrated detector (16) in order to estimate the oxygen consumption in said combustion and drawing from that consumption the amount of unburnt carbon in the ashes on the basis of a calibration.

tion already carried out in the invented apparatus.

3. A method for measuring the efficiency of a coal combustion wherein an analysis ash sample (2) is serially drawn in order to analyse every time an ash property related to the amount of the unburnt carbon contained in said ashes characterized in that it comprises the steps a) to f) specified in claims 1 and 2.

4. A method according to claims 1 to 3 characterized in that said laser beam is a beam of a CO<sub>2</sub> laser.

5. A method according to claims 1 to 4 characterized in that the time period for rising the temperature of said ashes to at least the carbon combustion temperature may be varied making the laser beam power to vary.

6. A method according to claims 1 to 4 characterized in that the time period for rising the temperature of said ashes to at least the carbon combustion temperature may be varied making the laser beam cross section to vary.

7. A method according to claims 1 to 4 characterized in that the time period for rising the temperature of said ashes to at least the carbon combustion temperature may be varied making the laser beam power and cross section to vary.

8. An apparatus for measuring the efficiency of a coal combustion according to the method specified in the preceding claims comprising a device (1) for drawing serially analysis ash samples (2) from a region of a combustion plant (3) characterized in that it comprises too: a reaction cell (4) sealed under control and having a filter-support (5) for supporting an analysis ash sample (2) supplied from said device (1); means (15) for exhausting said reaction cell (4); a comburent gas source (6) in communication with the inside of said reaction cell (4) in order to supply therein a controlled amount of comburent gas under controlled pressure; a source of said laser (11); an aperture (8) for passing said beam (12) of said laser (11) opposite to said filter-support (5) and closed by a plate (9) of a material which allows the laser beam (12) to pass through; means (13, 14) for directing said laser beam (12) on a surface (S) of the analysis ash sample (2) set on said filter-support (5) in order to burn the carbon contained in a superficial layer of said analysis sample; a detector (16) calibrated in the apparatus for measuring the carbon dioxide amount as contained in a gas; an exhauster (15) for drawing the gas from the inside of said reaction cell (4) in order to deliver it in said detector (16); an ejector (18) for removing the ash s of said ash sample (2) from the reaction cell (4) after combustion; a baffle plate (10) movable between a closing and an opening position, set between said aperture (8) and said filter-support (5) for being in a closing position while ashes enter said reaction cell (4) and

protecting said plate (9); means (17) for heating the reaction cell (4) in order to remove the possible humidity contained in the ash analysis sample(2).

9. An apparatus according to claim 8 characterized in that the detector (16) is calibrated in said apparatus for measuring the amount of oxygen in a gas.

10. An apparatus according to claims 1 and 2 characterized in that it comprises a first detector (16) calibrated for measuring the amount of carbon dioxide in a gas and a second detector (16) calibrated for measuring the amount of oxygen in a gas.

11. An apparatus according to any of the preceding claims characterized in that the laser source (11) is a CO<sub>2</sub> laser source.

12. An apparatus according to claim 11 characterized in that the power of said laser source (11) ranges from 20 to 30 watts.

13. An apparatus according to claims 8 to 12 characterized in that a programmed controller (C) is associated with the combustion plant (3), at least a calibrated detector (16) and all operative means of the apparatus in order to activate at predetermined time intervals the analysis steps according to claims 1 to 7 and optimize the combustion of the combustion plant (3) according to the analysis results as provided from at least one calibrated detector (16) and a predetermined program.
